# From period to lifetime budget constraint

- The period budget constraint is given by

$$c_t + a_{t+1} = (1 + r)a_t + x_t. \quad (\text{PB})$$

- We rearrange this equation

$$a_t = \frac{1}{1+r} (c_t - x_t + a_{t+1}). \quad (1)$$

- Forwarding this expression one period yields

$$a_{t+1} = \frac{1}{1+r} (c_{t+1} - x_{t+1} + a_{t+2}).$$

- We now plug this equation into (1)

$$a_t = \frac{1}{1+r} \left[ c_t - x_t + \frac{1}{1+r} (c_{t+1} - x_{t+1} + a_{t+2}) \right].$$

# Iterated substitution

- Rewriting this gives

$$a_t = \frac{1}{1+r} (c_t - x_t) + \left( \frac{1}{1+r} \right)^2 (c_{t+1} - x_{t+1} + a_{t+2}).$$

- We could then forward (1) one more period to substitute  $a_{t+2}$ .
- However, we can already see how the expression evolves when we repeat this procedure an infinite number of times, the result is

$$a_t = \sum_{s=0}^{\infty} \left( \frac{1}{1+r} \right)^{s+1} (c_{t+s} - x_{t+s}) + \underbrace{\lim_{s \rightarrow \infty} \left( \frac{1}{1+r} \right)^{s+1} a_{t+s+1}}_{=0 \text{ (by assumption)}}.$$

# No-ponzi game condition

- The condition

$$\lim_{s \rightarrow \infty} \left( \frac{1}{1+r} \right)^{s+1} a_{t+s+1} = 0$$

is called *no-ponzi game condition*.

- Multiplying by  $1+r$  and rearranging yields the lifetime budget constraint

$$\sum_{s=0}^{\infty} \left( \frac{1}{1+r} \right)^s c_{t+s} = (1+r)a_t + \sum_{s=0}^{\infty} \left( \frac{1}{1+r} \right)^s x_{t+s}. \quad (\text{LB1})$$

- From the lifetime budget constraint we can derive the period budget constraint again.

# From lifetime- to period budget constraint

- We rewrite the lifetime budget constraint (LB1) as

$$a_t = \sum_{s=0}^{\infty} \left( \frac{1}{1+r} \right)^{s+1} (c_{t+s} - x_{t+s}).$$

- Now, we “extract”  $c_t - x_t$  from the infinite sum

$$a_t = \frac{1}{1+r} (c_t - x_t) + \sum_{s=1}^{\infty} \left( \frac{1}{1+r} \right)^{s+1} (c_{t+s} - x_{t+s}).$$

- Rewriting this gives

$$a_t = \frac{1}{1+r} (c_t - x_t) + \underbrace{\frac{1}{1+r} \sum_{s=0}^{\infty} \left( \frac{1}{1+r} \right)^{s+1} (c_{t+1+s} - x_{t+1+s})}_{=a_{t+1}}.$$

# Back to the period budget constraint

- Substituting  $a_{t+1}$  gives

$$a_t = \frac{1}{1+r} (c_t - x_t) + \frac{1}{1+r} a_{t+1}.$$

- Multiplying by  $1+r$  and rearranging yields the period budget constraint

$$c_t + a_{t+1} = (1+r)a_t + x_t. \quad (\text{PB})$$

# Contents

- 4 Problem 4 (Optimal taxation)

# Maximization problem

- The representative household maximizes

$$\max_{\{c_{t+s}\}_{s=0}^{\infty}} \mathbb{E}_t \sum_{s=0}^{\infty} \beta^s U(c_{t+s})$$

subject to

$$c_t + a_{t+1} = (1 + r)a_t + x_t. \quad (\text{PB})$$

with period utility function

$$U(c_{t+s}) = c_{t+s} - \frac{\alpha}{2} c_{t+s}^2.$$

- The Lagrangian to this problem is

$$\mathcal{L} = \mathbb{E}_t \sum_{s=0}^{\infty} \{ \beta^s U(c_{t+s}) + \lambda_{t+s} [(1+r)a_{t+s} + x_{t+s} - c_{t+s} + a_{t+s}] \}.$$

## FOCs

- The first order conditions to the problem are

$$\frac{\partial \mathcal{L}}{\partial c_{t+s}} = \mathbb{E}_t [\beta^s (1 - \alpha c_{t+s}) - \lambda_{t+s}] \stackrel{!}{=} 0 \quad (\text{I})$$

$$\frac{\partial \mathcal{L}}{\partial a_{t+s+1}} = \mathbb{E}_t (\lambda_{t+s} - (1+r)\lambda_{t+s+1}) \stackrel{!}{=} 0. \quad (\text{II})$$

- Substituting the  $\lambda$ s in (II) by an expression obtained from (I) gives

$$\begin{aligned} \mathbb{E}_t [\beta^s (1 - \alpha c_{t+s})] &= (1+r) \mathbb{E}_t [\beta^{s+1} (1 - \alpha c_{t+s+1})] \\ \Leftrightarrow \mathbb{E}_t [(1 - \alpha c_{t+s})] &= (1+r) \beta \mathbb{E}_t [(1 - \alpha c_{t+s+1})]. \end{aligned}$$

# Euler equation

- Writing the expression for period  $t$  yields the Euler equation

$$(1 - \alpha c_t) = (1 + r)\beta \mathbb{E}_t [(1 - \alpha c_{t+1})].$$

- When does expected consumption rise, i.e. when is the gross growth rate  $\mathbb{E}_t c_{t+1}/c_t > 1$ ?
- Note that (omitting the expectations operator for a moment)

$$\frac{c_{t+1}}{c_t} = (1 + g_c) > 1 \text{ if } g_c > 0$$

$$\frac{c_{t+1} - c_t}{c_t} = \frac{c_{t+1}}{c_t} - 1 = g_c,$$

where  $g_c$  is the growth rate and  $1 + g$  is the gross growth rate of consumption.

- $g_c$  is positive if  $c_{t+1} > c_t$ .

# When does expected consumption rise?

- The Euler equation in rewritten form is

$$\mathbb{E}_t \frac{1 - \alpha c_{t+1}}{1 - \alpha c_t} = \frac{1}{(1+r)\beta} \begin{matrix} \leq \\ \geq \end{matrix} 1.$$

- The expected growth rate is positive if  $(1+r)\beta > 1$ .
- The expected growth rate is negative if  $(1+r)\beta < 1$ .
- The expected growth rate is zero if  $(1+r)\beta = 1$ .

- 1 Problem 1 (Budget constraints)
- 2 Problem 2 (Consumption)
- 3 Problem 3 (Permanent income hypothesis)**
- 4 Problem 4 (Optimal taxation)

# Euler equation

- For simplicity we set  $(1+r)\beta = 1$ , the Euler equation as of period  $t$  is

$$c_t = \mathbb{E}_t c_{t+1}.$$

- Iterating forward we have

$$c_t = \mathbb{E}_t c_{t+1} = \mathbb{E}_t \mathbb{E}_{t+1} c_{t+2} = \mathbb{E}_t c_{t+2} = \dots = \mathbb{E}_t c_i = \dots.$$

- As we have already found in problem 2, expected consumption is constant over time.
- The lifetime budget constraint is

$$\mathbb{E}_t \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i c_i = (1+r)a_0 + \mathbb{E}_t \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i x_i. \quad (\text{LB2})$$

- Substituting the Euler equation gives

$$\sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i c_t = (1+r)a_0 + \mathbb{E}_t \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i x_i.$$

Solving for  $c_t$ 

- Note that  $c_t$  does not depend on  $i$ , thus we can pull it out of the sum

$$\begin{aligned}
 c_t \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i &= (1+r)a_0 + \mathbb{E}_t \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i x_i. \\
 \Leftrightarrow c_t \frac{1}{1 - \frac{1}{1+r}} &= (1+r)a_0 + \mathbb{E}_t \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i x_i. \\
 \Leftrightarrow c_t \frac{1+r}{r} &= (1+r)a_0 + \mathbb{E}_t \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i x_i. \\
 \Leftrightarrow c_t &= \underbrace{ra_0 + \frac{r}{1+r} \mathbb{E}_t \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i x_i}_{\text{lifetime wealth}}.
 \end{aligned}$$

annuity value of lifetime income

# Change in consumption

- Note that  $r/(1+r)$  is the *marginal propensity to consume*.
- It tells us by how much current consumption is increased when lifetime wealth changes.
- Compare it to  $c_1$  in the traditional Keynesian consumption function

$$C = c_0 + c_1 Y.$$

- We derive the change in consumption simply by subtracting  $c_{t-1}$  from  $c_t$

$$\Delta c_t = \frac{r}{1+r} \left[ \mathbb{E}_t \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i x_i - \mathbb{E}_{t-1} \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i x_i \right].$$

# Change in the information set

- We have derived

$$\Delta c_t = \frac{r}{1+r} \left[ \mathbb{E}_t \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i x_i - \mathbb{E}_{t-1} \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i x_i \right].$$

- Consumption changes ( $\Delta c_t \neq 0$ ) if an *unexpected* change in lifetime income has occurred.
- This means if the lifetime income expected as of period  $t$  is different from the same lifetime income expected as of period  $t - 1$  the household changes consumption.
- Expected changes in income do *not* influence household's consumption decision.

# Random walk income

- Consider income follows a random walk

$$x_t = x_{t-1} + \varepsilon_t.$$

- Start with period 0

$$x_1 = x_0 + \varepsilon_1.$$

- Iterating forward and plugging one equation into the other yields

$$x_2 = x_0 + \varepsilon_2 + \varepsilon_1.$$

- Doing this repeatedly gives

$$x_i = x_0 + \sum_{j=1}^i \varepsilon_j.$$

# Expected change in lifetime in income

- Now, we compute expectations as of period  $t$  and  $t - 1$

$$\mathbb{E}_t x_i = x_0 + \sum_{j=1}^t \varepsilon_j$$

and

$$\mathbb{E}_{t-1} x_i = x_0 + \sum_{j=1}^{t-1} \varepsilon_j.$$

- Note that  $\mathbb{E}_t \varepsilon_t = \varepsilon_t$ ,  $\mathbb{E}_{t-1} \varepsilon_t = 0$ .
- Plugging this result into the expression for  $\Delta c_t$  gives

$$\Delta c_t = \frac{r}{1+r} \left[ \sum_{i=0}^{\infty} \left( \frac{1}{1+r} \right)^i \varepsilon_t \right].$$

# The expression for $\Delta c_t$

- Since  $\varepsilon_t$  does not depend on  $i$ , we can write this as

$$\Delta c_t = \frac{r}{1+r} \frac{1}{1 - \frac{1}{1+r}} \varepsilon_t = \frac{r}{1+r} \frac{1+r}{r} \varepsilon_t = \varepsilon_t.$$

- If income follows a random walk, a shock to income has a one to one impact on consumption.
- Note however, that we assumed that income follows a random walk, i.e. that shocks to income last forever and are thus very persistent.

# Contents

- 1 Problem 1 (Budget constraints)
- 2 Problem 2 (Consumption)
- 3 Problem 3 (Permanent income hypothesis)
- 4 Problem 4 (Optimal taxation)**

# Distortionary taxes

- A tax is said to be distortionary if it changes the consumption decision.
- This means that a tax is distortionary if the relationship of consumption levels between two periods is affected by the tax.
- Thus, we analyze the Euler equation to decide if the tax is distortionary.
- In principle we could tax many things such as assets, the interest rate, or income.
- In this problem we consider a consumption tax  $\tau_C$ .

# The problem

- The consumer maximizes

$$\mathbb{E}_t \sum_{s=0}^{\infty} \beta^s \frac{c_{t+s}^{1-\sigma} - 1}{1-\sigma}$$

subject to

$$(1 + \tau_c)c_t + a_{t+1} = (1 + r)a_t + x_t. \quad (\text{TPB})$$

- The Lagrangian to this problem is

$$\mathcal{L} = \mathbb{E}_t \sum_{s=0}^{\infty} \beta^s \left\{ \frac{c_{t+s}^{1-\sigma} - 1}{1-\sigma} + \lambda_{t+s} [(1 + r)a_{t+s} + x_{t+s} - (1 + \tau_c)c_{t+s} - a_{t+s+1}] \right\}$$

## FOCs

- The first order conditions are

$$\frac{\partial \mathcal{L}}{\partial c_{t+s}} = \mathbb{E}_t \beta^s \left[ c_{t+s}^{-\sigma} - \lambda_{t+s}(1 + \tau_c) \right] \stackrel{!}{=} 0 \quad (\text{I})$$

$$\frac{\partial \mathcal{L}}{\partial a_{t+s+1}} = \mathbb{E}_t \left( -\beta^s \lambda_{t+s} + \beta^{s+1}(1+r)\lambda_{t+s+1} \right) \stackrel{!}{=} 0 \quad (\text{II})$$

- Rewriting (I) gives

$$\mathbb{E}_t \lambda_{t+s} = \mathbb{E}_t \frac{c_{t+s}^{-\sigma}}{1 + \tau_c} \Leftrightarrow \mathbb{E}_t \lambda_{t+s+1} = \mathbb{E}_t \frac{c_{t+s+1}^{-\sigma}}{1 + \tau_c}$$

- Plugging this into (II) gives

$$\mathbb{E}_t \frac{c_{t+s}^{-\sigma}}{1 + \tau_c} = (1+r)\beta \mathbb{E}_t \frac{c_{t+s+1}^{-\sigma}}{1 + \tau_c}.$$

# Euler equation

- $1 + \tau_c$  cancels on both sides.
- We write the Euler equation for period  $t$

$$c_t^{-\sigma} = (1 + r)\beta \mathbb{E}_t c_{t+1}^{-\sigma}.$$

- The tax  $\tau_c$  does not appear.
- The Euler equation does not change compared to a situation without the consumption tax  $\tau_c$ .
- Thus, the consumption tax is not distortionary.
