Beam Divergence

Obtaining Probabilities

Particle Identification

Testing the method

Conclusion

- CEDAR = Čerenkov light detected with 8 PMTs
- Particle identification using multiplicity cut manual“
- Does not work properly for divergent beams
- New method developed by J. Friedrich for 2009 Primakoff data
- Can this method be adapted to 2008 hadron data?

Influence of Beam Divergence

Particle Identification

Testing the method

Conclusion

- Parametrize beam divergence:

$$\text{„absolute value“ } r = \sqrt{dx^2 + dy^2} = \frac{1}{\Delta z} \sqrt{\Delta x^2 + \Delta y^2}$$

$$\text{direction } \varphi = \begin{cases} \arctan \frac{dx}{dy} + \frac{\pi}{2} & \text{für } y \geq 0 \\ \arctan \frac{dx}{dy} + \frac{3\pi}{2} & \text{für } y < 0 \end{cases}$$

Grouping the Photomultipliers

According to the direction φ one can distinguish two cases:

- Divergence points towards a certain PMT
- Divergence points between two PMTs

Conclusion

Counting the Hits

- Take a pure Kaonsample and a pure Pionsample
- For each single event (separately for π and K)
 - ❖ calculate r and φ for each CEDAR
 - ❖ group PMTs according to φ
 - ❖ count the hits in the single groups
 - ❖ fill histograms for number of hits in single groups in r -bins

COMPASS

Beam Divergence

Obtaining
Probabilities

Particle Identification

Testing the method

Conclusion

Getting the Probabilities

- take all the histograms
- normalize bin by bin with the total number of events in that r -range
- fit the histograms

⇒ We obtain probability distributions $P_{c,g,h_g}^{\pi,K}(r)$ for h_g hits in group g at CEDAR c

COMPASS

Beam Divergence

Obtaining
Probabilities

Particle Identification

Testing the method

Conclusion

Calculating the Likelihoods

To identify a particle one has to calculate likelihoods:

- calculate \hat{r} and $\hat{\varphi}$ of the particle
- group PMTs and count the hits
- multiply according probabilities $P_{c,g,h_g}^{\pi,K}(r)$ for the given distribution of hits
- take the logarithm
- do so for Kaon and Pion hypothesis

$$\log L^{\pi,K}(c) = \sum_g \log \left(P_{c,g,h_g}^{\pi,K}(\hat{r}) \right)$$

Particle Identification

Testing the method

Conclusion

Decision

Decide between hypotheses (π, K) according to $\log L$ values:

- $\log L^\pi(c) > \log L^K(c) \quad \mapsto$ Decision „Pion“
- $\log L^K(c) > \log L^\pi(c) + 4, 5 \quad \mapsto$ Decision „Kaon“
- no decision „?“

Combine decisions of both CEDARs

&	?	π	K
?	?	π	?
π	π	π	?
K	?	?	K
